**Key words:** *Arabidopsis* dynamin-like 2, chloroplast targeting, localization, GFP fusion protein

### Abstract

Dynamin-related proteins are high molecular weight GTPase proteins found in a variety of eukaryotic cells from yeast to human. They are involved in diverse biological processes that include endocytosis in animal cells and vacuolar protein sorting in yeast. We isolated a new gene, *ADL2*, that encodes a dynamin-like protein in *Arabidopsis*. The *ADL2* cDNA is 2.68 kb in size and has an open reading frame for 809 amino acid residues with a calculated molecular mass of 90 kDa. Sequence analysis of *ADL2* revealed a high degree of amino acid sequence similarity to other members of the dynamin superfamily. Among those members *ADL2* was most closely related to Dnm1p of yeast and thus appears to be a member of the Vps1p subfamily. Expression studies showed that the *ADL2* gene is widely expressed in various tissues with highest expression in flower tissues. *In vivo* targeting experiments showed that *ADL2*:smGFP fusion protein is localized to chloroplasts in soybean photoautroph cells. In addition experiments with deletion constructs revealed that the N-terminal 35 amino acid residues were sufficient to direct the smGFP into chloroplasts in tobacco protoplasts when expressed as a fusion protein.

### Introduction

Dynamin is a high-molecular-weight GTPase protein found in the rat brain [34]. Recently many proteins with a high degree of amino acid sequence homology to dynamin have been discovered in various organisms ranging from yeast to man [1, 7, 9, 12, 16, 18, 24, 42, 47, 54, 58]. The primary structures of these proteins are all similar. The N-terminal regions, where the GTP-binding motifs are located, are highly conserved among these proteins. However, the rest of the polypeptide sequences are less well conserved. Also, the biological processes in which these proteins are known to be involved are very diverse [10, 16, 18, 20, 21, 22, 26, 33, 41, 53, 57]. Thus, it appears that the dynamin-like proteins are a superfamily of high mole-

cular weight GTPase proteins. The superfamily can be divided into five subfamilies based on sequence similarities and biological functions: the dynamin, Vps1p, SDL, Mx1, and Mgm1p subfamilies. The dynamin subfamily includes three dynamin isoforms of rat and shibire of *Drosophila* [7, 9, 32, 34, 54]. Much attention has been given to the rat brain isoform, Dynamin I. In numerous studies it has been shown that Dynamin I is composed of multiple functional domains. One of them is the SH3 binding domain which interacts with many proteins [17, 22, 30, 35, 43]. Recently it has been shown that the protein-protein interaction through the SH3 binding domain plays an important role in endocytosis [48]. Another functional domain is the pleckstrin homology (PH) domain at the center of the molecule. It has been suggested that the PH domain is responsible for the membrane association of the molecule by phospholipid-protein interaction [15, 42, 44, 51, 59]. Immunolocalization studies with an-

The nucleotide sequence data reported will appear in the EMBL, GenBank and DDBJ Nucleotide Sequence Databases under the accession number AF012833.

tibodies against Dynamin I have clearly demonstrated that it is present at high concentration at the neck of the invaginated plasma membrane which eventually becomes vesicles [23, 49]. Based on this observation it has been proposed that Dynamin I plays a role in the severing of the neck of the invaginated plasma membrane, thus generating the vesicles during endocytosis. In addition to the two domains discussed so far, Dynamin 1 has a GTPase activity that can be regulated by various means [19, 40, 46, 52] and is critical for endocytosis [10, 22]. Similarly, the *Drosophila* homologue shibire is also thought to be involved in endocytosis [39]. However, other proteins of this subfamily such as the ubiquitously expressed Dynamin II and the testis-specific Dynamin III have been less well characterized with regard to their *in vivo* roles, although Dynamin II has been shown to be localized to the Golgi apparatus [29]. Another well characterized subfamily includes the yeast homologues Vps1p and Dnm1p. Vps1p plays a role in vacuolar protein sorting [56, 57]. It has been proposed that during this process Vps1p participates in the formation of Golgi-derived vesicles which are destined to become vacuoles. Unlike Vps1p, Dnm1p is involved in the endocytotic pathway in yeast [16]. Another dynamin-related protein in yeast is Mgm1p. It forms its own subfamily and is the most distant member of the dynamin superfamily with respect to sequence homology as well as biological function. It plays a role in the maintenance of mitochondrial DNA [20]. Interestingly the molecule has a putative mitochondrial targeting sequence at the N-terminus that is homologous to the bacterial ribonuclease inhibitor, barstar [36]. In addition to the proteins described above, two new genes have recently been identified in plants: *SDL* and *ADL1* [12, 18, 38]. These proteins constitute a separate subfamily. Both of these plant proteins are shown to be associated with membranes and to form a high molecular weight complex *in vivo* [19, 38]. The biological role of the protein encoded by the *ADL1* gene of *Arabidopsis* is thought to be involved in the biogenesis of thylakoid membranes [37] whereas the soybean homologue *SDL* seems to be involved in the transport of materials to the cell division plate [19]. However, the detailed mechanism by which *SDL* participates in the transport of materials remains to be elucidated.

In the rat three isoforms of dynamin have been isolated and shown to be differentially expressed. Also, three dynamin-related proteins have been isolated for yeast. Since multiple isoforms of dynamin homologues might also be present in plant cells, we at-

tempted to clone additional genes encoding dynamin-like proteins in *Arabidopsis*. A search through the *Arabidopsis* EST database revealed that there were indeed ESTs that could potentially encode dynamin-like proteins in *Arabidopsis*. Here we report the cloning of an additional cDNA, *ADL2*, that encodes a dynamin-like protein in *Arabidopsis* that is localized to the plastids.

## Materials and methods

### *Screening for cDNAs encoding dynamin-like proteins*

The probe for the screening for cDNAs encoding dynamin-like proteins in *Arabidopsis* was prepared by PCR amplification using primers designed based on the nucleotide sequence information deposited in the dbEST database (GenBank accession number, Z29201). The primers were: *ADL2*-5': CAGATATCTCGTTTGTTA; *ADL2*-3': GGATGTGAAGTGTTTATG. First total RNA was reverse-transcribed to complementary DNA in the following conditions: 2  $\mu$ g of total RNA, 10 ng of *ADL2*-3' primer, 100 units of superscripts reverse transcriptase (BRL, USA), 0.5 mM dNTPs, 10 units of RNase Inhibitor (Promega, USA) in a 20  $\mu$ l of reaction volume at 37 °C for 1 h. To obtain an *ADL2* probe PCR reaction was performed with 2  $\mu$ l of the reverse-transcription mixture or 0.1  $\mu$ g of genomic DNA, 50 ng of each primer in a 100  $\mu$ l of reaction volume at the following parameters: 30 s denaturation at 94 °C, 30 s annealing at 45 °C, and 30 s elongation at 72 °C for a total of 50 cycles. The PCR products were gel purified and subcloned into pBluescript. Partial nucleotide sequencing was carried out to confirm the PCR products. Subsequently, we screened a lambda cDNA library with the PCR product as the hybridization probe after PCR labeling [14]. Positive plaques were isolated and inserts were excised as pBluescript clones. The insert sizes of the positive clones were compared by digestion with *EcoRI* and *XhoI* and the clone with the largest inserts was selected for further characterization. After confirming the clone by sequencing the 3' and 5' ends, serial deletion constructs were generated for full sequencing. The sequencing was done by PCR sequencing using the dideoxy dye terminator according to the manufacturer's protocol (ABI, USA). The nucleotide sequences were read by an automatic sequencing apparatus (ABI, USA).

### Northern and Southern blot hybridization

Total RNA was isolated from various tissues by the phenol/LiCl method as described previously [3]. A 20  $\mu$ g portion of total RNA was separated on a 1.2% formaldehyde-agarose gel and blotted onto a nylon membrane. For Southern blot analysis genomic DNA was isolated and 3  $\mu$ g of the DNA digested with the appropriate restriction endonucleases. The digested DNA was separated on a 0.8% agarose gel and transferred onto a nylon membrane. The blots were hybridized according to a protocol described previously [8].

### Growth of plants

*Arabidopsis thaliana* (ecotype Columbia) was grown in a greenhouse under the conditions of a 16/8 h light/dark cycle, a temperature of 20 °C, and a relative humidity of 70%. Some plants were grown on MS plates in a growth chamber at 20 °C with a 16/8 h light/dark cycle. Soybean suspension cells (soybean photoautotrophic cells, SB-P) were grown at 25 °C with constant shaking and with a 16/8 h light/dark cycle. Tobacco plants were grown on MS medium supplemented with 2% sucrose in culture bottles at 25 °C with 16/8 h light/dark cycle.

### Transformation of fusion constructs into plant cells

Chimeric fusion constructs, *ADL2:smGFP*, *ADL2-BH::smGFP*, and *ADL2EvH:smGFP*, were generated for targeting experiments using standard recombinant technology [3]. A full-length *ADL2* cDNA without the termination codon was prepared by PCR amplification using the *ADL2* cDNA in pBluescript as a template. The primers for the PCR amplification were the T3 primer for pBluescript and a specific primer, *ADL2-end* (5'-CCTCGAGGAATCGTATCCATTTTG-3') that eliminated the termination codon. To generate *ADL2BH:smGFP* and *ADL2EvH:smGFP* fusion constructs, the *Bam*HI fragment (200 bp) and *Eco*RV fragment (364 bp) were fused with the coding region of *smGFP* [11]. Transient expression of GFP fusion constructs was carried out after introducing the DNAs into tobacco protoplasts of leaf cells by the PEG-mediated transformation [45] or soybean suspension cells (soybean photoautotrophic cell, SB-P) by the particle bombardment method [4, 50]. Expression of the introduced DNA was examined at various time points after trans-

formation and photographs were taken with a Zeiss Axiophot fluorescence microscope.

## Results

### Isolation of cDNA clones encoding a dynamin-like protein

In the course of looking at intracellular trafficking in plants, we had cloned and characterized *ADL1* from *Arabidopsis* [38]. To widen our approach we decided to clone additional genes encoding dynamin-like proteins in *Arabidopsis thaliana*. A search through the EST analysis files (University of Minnesota Plant Molecular Informatics Center, USA) resulted in the identification of 12 EST clones with significant sequence homology to dynamin [2]. The analysis of these EST clones suggested that there may be at least 3 additional isoforms of dynamin-like protein genes in *Arabidopsis*. We decided to isolate these genes with the PCR approach. We designed oligonucleotides corresponding to the 5' and 3' end of the EST clone, VBVF04, and used them to generate a hybridization probe by PCR. The RT/PCR amplification from total RNA resulted in a PCR product of 240 bp. Also, PCR amplification using genomic DNA produced a PCR product that was slightly larger than that generated from total RNA (data not shown), indicating that there may be an intron. These PCR products were used to screen an *Arabidopsis*  $\lambda$ ZAPII cDNA library. We obtained 10 positive clones and pBluescript clones were excised from the  $\lambda$  clones. We named the cDNA clones *ADL2* (*Arabidopsis* dynamin-like 2). The cDNA clone with the largest insert was selected and the nucleotide sequence was determined using a dye terminator sequencing kit. The size of the *ADL2* cDNA was 2.68 kb. The first methionine codon was located at the nucleotide position 95 followed by 2.43 kb of an open reading frame and 161 bp of the 3'-untranslated region.

### Sequence analysis of *ADL2*

The nucleotide and deduced amino acid sequences of the *ADL2* cDNA are shown in Figure 1. *ADL2* has an open reading frame of 2430 bp that encode 809 amino acid residues with a calculated molecular mass of 90 kDa. The size of *ADL2* is larger than that of *ADL1/aG68* which has 610 amino acid residues with a calculated molecular mass of 68 kDa. The soybean homologue, *SDL*, also has a similarly smaller size

Figure 2. Sequence alignment of ADL2. The amino acid sequence of ADL2 was aligned with the sequences of Dnm1p, Vps1p, and aG68 using the multiple alignment program of DNASIS. Gaps were introduced to maximize identity. Amino acid residues in common with those of ADL2 are indicated by upper case type. I1, and I2 indicate 29 and 45 amino acid insertions, respectively. The *Bam*HI and *Eco*RV sites indicate the restriction sites used to make deletion constructs for the fusion proteins between ADL2 and smGFP as shown in Figure 7.

with 610 amino acid residues [18]. The primary amino acid sequence of ADL2 reveals that it has a structure with similarities to other members of the dynamin superfamily, namely the highly conserved GTP-binding domain in the N-terminal region and the less well conserved region at the C-terminus. However, ADL2 appears not to have the proline-rich SH3 binding do-

main found in rat Dynamin I and which has been implicated in protein-protein interaction. It is also not clear, whether ADL2 has the other important functional domain, the PH domain which has been shown to interact with phospholipids *in vitro*. In most cases, it is rather difficult to recognize the PH domain in the amino acid sequence by simple inspection of the pri-

Sdl (U25547), aG68 (S59558), Dyn1 (p21575), Vps1 (P21576), Dyn3 (Q08877), Human II (L36983), Shibire (P27619), Pombe (Q09748), Dnm1 (P54861), *C. elegans* (U61944), Mx1 (P20591), Mgm1 (S33918)

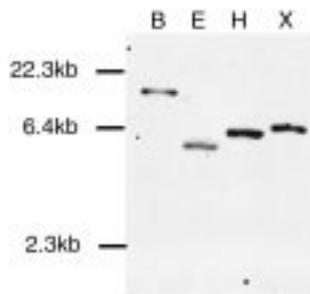

Figure 4. Southern blot analysis of the *ADL2* gene. Genomic DNA was isolated from the Columbia ecotype and 3  $\mu$ g of the genomic DNA was digested with restriction endonucleases. The digested DNA was separated on a 0.8% agarose gel, blotted onto a nylon membrane, and UV cross-linked. Hybridization was carried out at 65 °C with the randomly labeled cDNA as the hybridization probe. B, *Bam*HI, E, *Eco*RI; H, *Hind*III; X, *Xho*I.

mary sequence due to the low degree of amino acid sequence conservation in spite of the fact that the PH domains of various proteins have remarkably similar tertiary structures [15].

#### Sequence comparisons of *ADL2*

The deduced amino acid sequence of *ADL2* was compared to those deposited in the public databases using the Blastx program provided by the NCBI e-mail server [2]. *ADL2* exhibited 38%, 35%, and 26% sequence similarity to Dnm1p [16], Vps1 [41], and aG68/*ADL1* [12, 38], respectively. Interestingly *ADL2* was more closely related to the yeast proteins Dnm1p and Vps1p than to the plant homologues *ADL1/aG68* and *SDL*. The aligned sequences

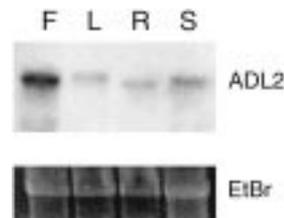

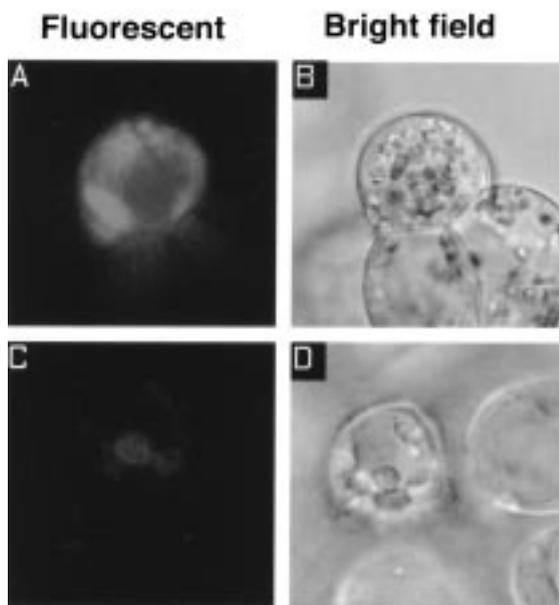

Figure 5. Expression of the *ADL2* gene. A. Total RNA (20  $\mu$ g) isolated from various tissues was separated on a 1.2% formaldehyde/agarose gel, blotted onto a nylon membrane, and UV cross-linked. Hybridization was at 65 °C overnight to the randomly labeled cDNA as a probe. F, flower; L, leaf; R, root; S, siliques. To check for equal loading, the gel was stained with EtBr before blotting.

of *ADL2*, Dnm1p, Vps1p, and aG68 are shown in Figure 2. The sequence comparison revealed that *ADL2* shared the highest degree of amino acid sequence homology in the region containing the GTP-binding motifs. It is known that the homology between the members of the dynamin family is usually limited to the N-terminal region. However, the homology between *ADL2* and Dnm1p extends beyond the GTPase domain to the C-terminal region, indicating an even closer relationship between *ADL2* and Dnm1p. Close inspection of the sequence alignment revealed additional features. It has been noticed that Vps1p and Dnm1p have 47 amino acid residues inserted between the first and second motif of the GTPase motifs, resulting in an unusually long spacing between the first and the second motif of the GTPase domain [16]. This insertion is absent in *ADL2*. Instead *ADL2* has other

**Figure 6.** *In vivo* targeting of *ADL2::smGFP* fusion constructs. The fusion constructs were introduced into SB-P cells by the particle bombardment method and the cells were incubated for 6 h. The soybean cells were examined with a Zeiss fluorescence microscope. Photographs were taken with the Zeiss Axiophot fluorescence microscope. Panels A and B are fluorescent and bright-field images of soybean cells transformed with *ADL2::smGFP*, respectively. Panels C and D are fluorescence and bright field images of soybean cells transformed with *smGFP*, respectively.

insertions in both the N- and C-terminal region. The 29 amino acid insertion (I1 in Figure 2) in the N-terminal region is high of proline and serine content. Sequence comparison revealed that this insertion is present only in *ADL2* among the members of the dynamin family. The amino acid sequence composition of the 29 amino acid insertion resembles that of chloroplast transit peptides [5, 27, 55]. It has been shown that the chloroplast transit peptide has a high content of uncharged residues such as serine. Indeed this insertion behaved as a transit peptide for chloroplast targeting (see the targeting of *ADL2::smGFP* fusion protein below for detail). Also, the C-terminal region of *ADL2* has an extension of 45 amino acid residues (I2 in Figure 2) in comparison to *Vps1p* and *Dnm1p*. At this moment it remains to be seen whether any functional significance can be attributed to the insertions. To investigate further the relatedness of *ADL2* to other members of the dynamin superfamily, we constructed a phylogenetic tree using the multiple alignment program of DNASIS. As shown in figure 3, *ADL2* seems to belong to a subfamily made up of the two yeast proteins *Vps1p* and *Dnm1p*, homologues of *Caenorhabditis elegans*

and *Schizosaccharomyces pombe*. However, it is not clear at this time whether the relatedness of the amino sequences of these polypeptides reflects a functional similarity as well.

#### *Genomic structures of the ADL2 gene*

To understand the genomic structure of the *ADL2* gene, Southern blot analysis was carried out with the cDNA as the hybridization probe. Genomic DNA was isolated from the Columbia ecotype and digested with several restriction endonucleases. Hybridization was carried out under high stringency conditions. As shown in Figure 4, the *ADL2* cDNA appeared as a single band or double bands, suggesting that the *ADL2* gene may be present as a single copy in the genome. When the hybridization was carried out under lower-stringency conditions, there were very weak additional signals (data not shown), suggesting that, if there are any related genes, they may be only distantly related to *ADL2*.

#### *Expression of the ADL2 gene*

To gain insight into the expression of the *ADL2* gene, we undertook a northern blot analysis using total RNA prepared from various tissues. The whole cDNA was labeled by the random labeling method [14] and used as hybridization probe under the conditions used for the Southern blot analysis. As shown in Figure 5, the *ADL2* gene was expressed in all the tissues we examined. However, there were differences in the level of expression. The highest expression was seen in flower tissue. In a previous study with the *aG68/ADL1* gene, it had been shown that the gene too was expressed in all tissues examined with different levels of expression [12, 38].

#### *Targeting of ADL2::smGFP fusion proteins*

The sequence analysis of *ADL2* strongly suggested that *ADL2* may be localized to plastids. To investigate this possibility further, we tried to localize the protein *in vivo*. A fusion construct was generated between the *ADL2* cDNA and the *smGFP* gene [11] and introduced into soybean suspension cells (SB-P) by the particle bombardment method [50]. Localization of the fusion protein was observed under a fluorescence microscope. As shown in Figure 6, the fusion protein was localized to the plastids of the soybean cells whereas the control *smGFP* was uniformly distributed in the cytosol. Therefore to further define

Figure 7. Diagrams of the fusion constructs between *ADL2* and *smGFP*. A, *ADL2:sm:GFP*; B, *ADL2EvH:smGFP*; C, *ADL2BH:smGFP*; D, *smGFP*. 35Spr and nos-t indicate the CaMV 35S promoter and nos terminator, respectively. The restriction sites that were used to construct the deletion mutants are indicated on Figure 2.

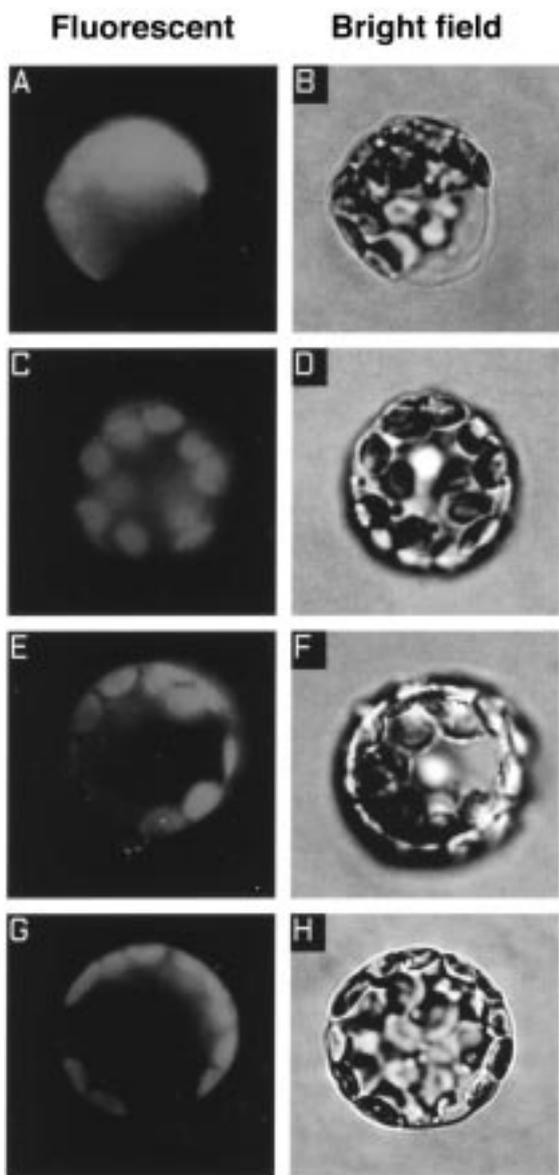

the sequence element necessary for the targeting of the protein to plastids deletion constructs of *ADL2* were generated and fused to *smGFP* as shown in Figure 7. The *ADL2BH:smGFP* and *ADL2EvH:smGFP* fusion constructs contained 35 and 90 amino acid residues from the N-terminus, respectively. The fusion constructs were introduced into tobacco leaf cell protoplasts by the PEG-mediated transformation [46]. Localization of the fusion protein was observed with a fluorescence microscope. The introduced fusion genes that were under the control of the CaMV 35S promoter were expressed strongly in the tobacco protoplasts. As shown in Figure 8, all three *ADL2:smGFP* fusion proteins were clearly localized to the chloroplasts of tobacco protoplasts whereas the control GFP was uniformly distributed. Also, the localization pattern of the *ADL2:SMGFP* fusion proteins was identical to that of the *Cab:smGFP* fusion protein (data not shown). To investigate whether the fusion protein is localized inside the chloroplasts, the protoplasts were lysed and treated with proteinase K. The released chloroplasts remained fluorescent in the presence of proteinase K (data not shown), suggesting that the fusion protein is indeed inside the chloroplasts. Therefore, the *in vivo* targeting experiments with the deletion constructs suggested that *ADL2* is targeted into the plastids and that the first 35 amino acid residues are sufficient for the targeting of *ADL2* into the plastids.

## Discussion

The existence of multiple isoforms of dynamin-like proteins has been known for the rat, for *Drosophila*, and for yeast [7, 16, 29, 32]. However, these multiple isoforms are generated by different mechanisms. In the rat the highly homologous isoforms of dynamin are encoded in three separate genes which are expressed

differentially in different tissues [9, 32, 34]. In addition, the primary transcripts of these rat genes are also alternatively processed to yield multiple mRNA species [40]. In *Drosophila*, the *shibire* gene too is alternatively spliced in a tissue-specific manner resulting in multiple isoforms [7]. In yeast there are three genes, *VPS1*, *DNM1*, and *MGM1*, that encode dynamin-like proteins [16, 26, 41]. The amino acid sequences of the dynamin-like proteins show considerable differences and the proteins are involved in different biological processes. In this study we isolated a new gene encoding a dynamin-like protein from *Arabidopsis*. Sequence analysis of *ADL2* revealed that it is a new member of the dynamin family. As is the case with other members of the dynamin family, *ADL2* has the highly conserved GTP-binding motifs in the N-terminal region, while the rest of the molecule diverges. The *ADL2* sequence is most closely related to the yeast *Dnm1p* with homology extending beyond the highly conserved GTP-binding domains. Thus, *ADL2* can be grouped into the *Vps1p* subfamily. Alignment of the *ADL2* sequence with *Dnm1p* and *Vps1p* revealed two insertions in both the N- and the C-terminal region. The N-terminal insertion has a relatively high content of proline and serine. In the case of the rat dynamins, the proline rich motifs in the C-terminal region have been shown to be involved in the interaction with a subset of SH3 domains in various proteins [35, 43].

Although *Dnm1p* and *Vps1p* are members of the same subfamily, these proteins are involved in different biological processes. *Dnm1p* is involved in the very early stage of the pheromone-mediated endocytotic pathway in yeast [16], whereas *Vps1p* is involved in vacuolar protein sorting [41]. It is not clear whether *ADL2* shares any functional similarities with these proteins. The *in vivo* targeting experiment with the *ADL2:smGFP* fusion constructs revealed that

**Figure 8.** The N-terminal 35 amino acid residues are sufficient for the chloroplast targeting. The fusion constructs were introduced into tobacco leaf protoplasts by the PEG-mediated transformation method and the protoplasts were incubated for 6 to 12 h in the dark. The protoplasts were observed under a fluorescent microscope (Axiophot, Zeiss). Fluorescent (left panels) and bright-field images (right panels) are shown for smGFP (A, B), ADL2:smGFP (C, D), ADL2EvH:smGFP (E, F), ADL2BH:smGFP (G,H).

the fusion proteins were localized at the chloroplasts in tobacco leaf protoplast as well as in soybean suspension culture cells. Interestingly, another dynamin homologue, ADL1 of *Arabidopsis* has shown to be localized to thylakoid membranes of chloroplasts [37]. Dynamin family members are thought to play roles in vesicle formation in a variety of seemingly unrelated processes. The data of the *in vivo* localization experiments thus raise the possibility that ADL2 is involved in vesicle formation in the chloroplasts. In fact it has been demonstrated there is vesicle formation in the chloroplasts. These vesicles were more clearly visible when the leaf tissues of tobacco and pea were incubated at lower temperatures before processing for electron microscope [31]. Also, Hugueney *et al.* [25] have isolated a protein, Pftf, that is involved in the vesicle fusion in the chromoplast of red pepper. It has long been suggested that vesicles could be a means to transport a large amount of lipids from the inner membrane of the chloroplast envelope into the thylakoid membranes during thylakoid membrane biogenesis [6, 13, 31]. Thus, it may be possible that ADL2 is involved in this process. In addition, there are a large number of evidences for the presence of an endomembrane system in the plastids [28]. Therefore, it is equally possible that ADL2 may be involved in the formation of vesicles in this endomembrane system within the plastids.

The transcriptional expression study of the *ADL2* gene revealed that the gene is expressed in all the tissues we examined, but there were differences in the levels of the *ADL2* transcript in the various tissues. The *ADL2* transcript level was highest in flower tissue. However, the flower tissue used for the isolation of total RNA included many different cell types. It will be necessary to define the exact cell type where this gene is most strongly expressed.

### Acknowledgements

The clone for smGFP (CD3-326) was provided to us by the Arabidopsis Biological Resource Center at Ohio State University (USA). This work was supported in parts by a grant from the Genetic Engineering Fund of the Ministry of Education (GE97-26) and by a grant from KOSEF to PMBBRC.
